

Analyzing Pedestrian and Cyclist Collisions and Overall Safety from 2006 to 2022 in Toronto*

Cristina Burca

January 23, 2024

This paper examines trends of cyclist and pedestrian collisions in Toronto from years 2006-2022. This paper is meant to infer on patterns of injuries and their severities, and attempt to interpret the cause for the trend of these accidents. We will investigate how the city of Toronto is navigating solutions to these trends. Results show a general downward trend of overall injuries, due to various circumstances.

1. Introduction

Toronto stands among the many cities that have been advocating for more eco-friendly commuting practices among its citizens. A key aspect of this initiative involves the promotion of alternative modes of transportation, such as cycling, walking, and utilizing public transit options. The city has taken measures to implement and enforce these commuting alternatives, including the constant integration of bike lanes on city roads and the introduction of rentable city bikes, with hubs conveniently placed around the city for pickup and return of the bikes. Besides a means of commuting to work, the city also encourages citizens to explore these options under favorable weather conditions or when venturing out to local events or shops of shorter distances.

“There’s data to show that when we have bike lanes, car-to-car collisions go down along those streets, as do collisions and impacts on people walking,” said Jacquelyn Hayward, Toronto’s Director of Transportation Project Design & Management (Braun 2021). In 2016, Toronto launched a network plan named Vision Zero to install safety initiatives with the goal of decreasing driving collisions and fatalities, with a specific focus on children, older citizens, pedestrians, and cyclists (Toronto 2016). 650 kilometers of trail, bike, and pedestrian lanes and paths have been funded by the government of Canada, and 15 kilometers of bike lanes have been established in the city of Toronto in 2018 and 2019. But have these efforts by the city of Toronto led to an increase in cyclists and pedestrians?

Inherit issues such as heavy traffic, ongoing construction, unsafe road conditions, and the alarming number of vehicle and pedestrian accidents cause citizens to be apprehensive to walk or cycle down the streets of Toronto. “Toronto is the most perilous city in the world to be a cyclist,” states Henry Gold, “it’s more dangerous than anywhere else in the world,” (Murphy 2018). Council Mike Layton says that people should not be afraid to leave their homes and walk on the street because they are in fear of an accident. Clearly, there is uncertainty that this over \$87 million project Vision Zero has made an impact on the number of pedestrian and cyclist collisions and fatalities. For citizens to take advantage of initiatives the city of Toronto has implemented to make pedestrians safer, they must not question whether these measures are effective or not.

From here, I will analyze if there has been any overall change in pedestrian and cyclist collisions and fatalities in the city of Toronto, as well as the severity of injuries, to overview the trends of these variables over the years, as well as to infer on the city’s Vision Zero plan, and give insight on the safety conditions for pedestrians and cyclists.

2. Data

In this section, I will explain the contents of the data, the variables considered, and observations made from analyzing the data.

2.1 Introducing the data

The data used for this paper has been retrieved from the City of Toronto Open Data Portal (Gelfand 2022), titled “Motor Vehicle Collisions involving Killed or Seriously Injured Persons” (Data 2023). It includes driving collisions recorded from 2006 to 2022, listing 50 variables about the collisions such as location, people involved and age, weather conditions, driver actions, speed, and injuries. Data was cleaned and analyzed using R (R Core Team 2021), using functions from the following packages: knitr (Xie 2014), tidyverse (Wickham et al. 2019), and lubricate (Grolemund and Wickham 2011).

2.2 Variables of interest

Since I am comparing pedestrian and cyclist collisions, I have filtered the data to show only pedestrian and cyclist collisions, and have selected the variables ‘Date’ and ‘Injury’ to study. ‘Date’ is formatted as YYYY-MM-DD and ‘Injury’ lists the severity of the injury of the cyclist or pedestrian from ‘None’, ‘Minimal’, ‘Minor’, ‘Major’ and ‘Fatal’. ‘DRIVACT’, ‘PEDACT’ and ‘CYCACT’ are variables that I have decided to include, which list the actions of the respective person, whether they were driving/ cycling/ walking properly, made an illegal action, etc. I then created two new columns titled ‘Year’ and ‘Month’, to separate the year and month information to allow for easier comparison of years and months.

As a slight overview, I printed the number of injuries (not including fatalities) and fatalities in Figure 1 to get an idea of the trend. It is clear that the number of injuries is on an overall decline, as well as the number of fatalities, but with a spike in fatalities between 2013-2019. However, this is just some rough insight and I shall analyze the data more rigorously.

3 Analysing the data

In this section, I will graph the data accordingly, analyzing the variables and any trends or correlations that may occur.

3.1 Injuries and fatalities overtime

Firstly, I want to explore the general trend of injuries and fatalities over the years of 2006 to 2022. We saw in Figure 1 that the general trend of injuries is on a decline. Lets observe this on a line graph.

Observing Figure 2, we notice the general decline beginning in 2013, with a substantial decrease from 2013 to 2014, dropping from 672 to 419 injuries. It is notable that Toronto had a devastating flood in July of 2013. This decline persists throughout subsequent years, with the exception of 2018, where the number of injuries spikes to approximately 550.

Year	Injuries	Fatalities
2006	676	33
2007	575	25
2008	560	29
2009	567	32
2010	554	22
2011	599	20
2012	659	27
2013	672	46
2014	419	35
2015	435	43
2016	461	45
2017	469	41
2018	538	45
2019	476	40
2020	337	25
2021	210	29
2022	321	25

Figure 1: Number of pedestrian and cyclist injuries and fatalities by year

Figure 2: Line graph of cyclist and pedestrian injuries vs. fatalities from 2006 to 2022

3.2 Severity of injuries

I shall also observe the severity of injuries overtime.

Figure 3: Line graph of cyclist and pedestrian injuries from 2006 to 2022, listed by severity

In Figure 3, we fortunately notice that a large number of cyclist and pedestrian accidents are listed as no injuries, almost twice the accidents are ‘no injuries’. However, there are a great amount of accidents listed as ‘major accidents’. We notice a major drop in both no injuries and major injuries initiating in 2013. In 2013 to 2019, there was a higher number of fatal injuries recorded, with an average of 42 fatalities a year.

3.3 Observing years 2016 and after

I discussed earlier about Toronto’s Vision Zero plan, which was implemented in 2016. I shall observe the data of the years 2016 and on.

In Figure 4, we notice there is a spike of injuries in 2018. Leading up to this period, it appears that Toronto’s Vision Zero plan has not made an observable impact on pedestrian and cyclist collisions. As the incident count begins to decline, Covid-19 was introduced at the end of 2019, and lockdown was put in place in March 2020. This can describe the steady decline in accidents, as citizens were asked to limit their needs of driving, and asked to stay home whenever feasible. As lockdowns were officially lifted in June of 2021, a resurgence of accidents began again.

Figure 4: Line graph of cyclist and pedestrian injuries from 2016 to 2022, listed by severity

Year	% Injuries	% Fatalities
2016	26	2
2017	8	-4
2018	69	4
2019	-62	-5
2020	-139	-15
2021	-127	4
2022	111	-4

Figure 5: Table of cyclist and pedestrian injuries and fatalities differences from previous year, from 2016 to 2022

In Figure 5, I have outlined the rate of change of injuries and fatalities from each year to the next. Although there is a sharp decline from 2019 to 2021, the increase from 2021 to 2022 is fairly rapid.

4. Results

Overall, it is obvious to point out that the general trend of pedestrian and cyclist injuries from 2006-2022 is on a decline. The significant drop of injuries from 2013 to 2014 may be attributed to the unfortunate flood that struck Toronto in 2013. The city went underwent a process of rebuilding, and many citizens experienced significant losses.

We notice a spike of injuries in 2018 seen in Figure 4, implying that Toronto's Vision Zero plan had not produced an observable impact on collisions during 2016 to 2018. Moreover, there is a significant decline in accidents in 2019, most likely due to the introduction of Covid-19 and Ontario's stay at home orders until June 2021. While this data offers insight of accident rates from 2006-2022, it does not offer a lot of insight on the target years I was observing. This leads to an uncomprehensive view of the factors affecting pedestrian and cyclist safety.

Moreover, the post lockdown period from June 2021 reveals an 111% increase in accidents in Figure 5 after Covid-19 measures were lifted. It's important to acknowledge that this increase may be influenced by factors from the pandemic, however, this increase may be of concern to pedestrians and cyclists, as a jump this abrupt can be a safety concern. This abrupt jump in accidents post-lockdown needs further investigation to determine whether it stems from commuter behaviours, traffic patterns, or external influences that may require attention.
